Editorial

In an era where artificial intelligence (AI) is fundamentally reshaping the contours of knowledge creation and dissemination, libraries are no longer mere repositories of the analog past but vibrant forges of equitable, inclusive innovation. The Library Association of Bangladesh (LAB) International Conference on Reimagining Librarianship: Forging the Future with AI Technologies (ICRL), successfully held on 12–13 December 2025 at the historic Nabab Nawab Ali Chowdhury Senate Bhaban, University of Dhaka, Bangladesh, brought together more than 600 librarians, scholars, technologists, and policymakers from across the globe. Over two intensive days, participants engaged in critical discussions on the transformative potential of AI in librarianship while candidly addressing persistent challenges such as the global digital divide, ethical implications of algorithmic systems, data sovereignty, and the imperative of human-centered design in library services. The conference underscored that the future of librarianship lies not in resisting technological change but in actively shaping it to uphold the core values of access, equity, and intellectual freedom for all. The specific objectives of the ICRL were to explore nine key tracks: AI-enabled library operations and workflow automation; personalized services and user engagement; AI and innovative library services; AI in digital preservation and archiving; research, innovation, and future directions; ethical, legal, and privacy issues; capacity development and new literacies; community engagement with AI; and policy frameworks and changing job structures in the AI age. Serving as a vibrant international forum, the conference provided students, researchers, faculty members, and library and information professionals from around the world a welcoming platform to share fresh ideas, present original research findings, and exchange practical experiences across all areas of library and information science, including artificial intelligence, data science, big data, knowledge management, data mining, databases, and data visualization. This year, we received 41 research papers from authors in Bangladesh and India. Each submission underwent a rigorous peer-review process conducted by two independent reviewers under a single-blind protocol. The initial evaluations were deliberated among the reviewers and finalized by the convener of the conference's National Steering Committee. As a result, 21 papers (51.22%) were accepted as full papers, 3 papers (7.32%) as short papers, and 15 papers (36.59%) for publication as abstracts in the conference proceedings, while 2 papers (4.88%) were rejected.

We highly appreciate the conference organizing national steering committee members, all sub-committee members and external reviewers for their technical effort in providing straightforward comments and impartial judgment in the review process of ICRL-25. Our deepest gratitude goes to our distinguished Chief Guest, Professor Dr. Chowdhury

RafiqulAbrar, honorable Adviser, Ministry of Education, Interim Government of Bangladesh; the Guest of Honor, Professor Niaz Ahmed Khan, *PhD*, honorable Vice-Chancellor of the University of Dhaka; and the Special Guest, Dr. A. S. M. Amanullah, honorable Vice-Chancellor of the National University of Bangladesh, for their gracious presence at this conference. We extend our sincere gratitude to the keynote speaker, Emily Drabinski, immediate past president of the American Library Association and associate professor at the graduate school of information studies, City University of New York, USA, for her inspiring presence and invaluable contributions. We are confident that LIS scholars and professionals worldwide will remain deeply grateful for her steadfast commitment and collaborative spirit. Finally, we extend our heartfelt thanks to all authors and conference participants for their invaluable contributions and unwavering support. We hope that everyone seized this opportunity to share and exchange ideas with fellow scholars, while enjoying ICRL-25 on the splendid campus of the University of Dhaka, Bangladesh.

Due to time constraints, there may be some typographical errors or inaccuracies. We sincerely apologize for any oversights. We firmly believe that these proceedings are more than mere reading material—they serve as a catalyst for reflection and action. As AI reshapes the landscape of libraries, we must navigate this transformation with thoughtful stewardship to ensure equity and sustainability for all. The papers in these proceedings advance us from superficial AI integrations to authentic partnerships: ethical, inclusive, and profoundly transformative. Our deepest thanks go to all our supporters, particularly the University of Dhaka for waiving the additional charges for the conference hall, and to our sponsors for their generous financial contributions. May these insights ignite meaningful progress, illuminating the path for libraries to lead us through the era of AI.

Transforming the User Experience: AI-Powered Services in the Modern Library

Sayed Mahbub Hasan Amiri¹

Abstract

The 21st-century library is being redefined: from a physical location-based entity to a digital-based service, the library is transforming from a resource-cantered space to a knowledge-cantered space. The massive impact of AI is transforming not only the delivery of services but also the way users interact with services. This research systematically investigates on the effects of AI-enabled services on user experience (UX) in futuristic libraries. It has three purposes: to outline the most important relevant applications of AI in library practice; to discuss critically their impact on certain core aspects of the UX (accessibility, efficiency, personalization and engagement); and to consider related implications for future service models, evolving professional roles and ethical AI implementation frameworks. Utilizing a qualitative descriptive research approach, this study is informed by a systematic review of the literature consisting of peer-reviewed articles, conference proceedings, and institutional case studies from 2018-2024. Source data were extracted from major academic databases and thematic analysis was performed to integrate the findings across the 4 predominant AI services. The report shows that AI improves UX through 24/7 access with smart chatbots, which are able to manage routine queries. In a similar way, personalisation powered by AI in e-learning and discovery solutions enables the tailoring of material to the needs and preferences of each user, making the experience more immersive and effective. Semantic searching reduces user frustration, and automation in digital repositories democratizes access to special collections. However, such integration also faces a few difficulties and issues, such as algorithmic bias, data privacy and the potential for widening the digital divide. The paper makes the case for a symbiotic service model in which AI handles scale and routine tasks, freeing human librarians to engage in complex consultation, ethical oversight, and community involvement. AI is a transformational technology for libraries that enables a move from transactional focused to proactive, personalized services. An effective uptake of this trend will rest upon planning and resourcing for its support on an ongoing basis as well as unambiguous and unwavering adherence to ethical tenets as libraries evolve as open and dynamic institutions in the digital era.

Keywords

Artificial Intelligence, Library Services, User Experience, Intelligent Chatbots, Discovery Tools, Digital Repositories.

1. Introduction

Today's library is changing from a repository of physical materials to a user-centred knowledge-creation digital and community-innovative hub (IFLA, 2023). This shift is in response to the demands of the information environment, changing libraries' perception of value from collection-cantered to experience-cantered. The modern library is no longer just a place to access information but rather a space to create information. The library is

¹ Lecturer, Department of ICT, Dhaka Residential Model College, Mohammadpur, Dhaka, Bangladesh. Email: amiri@drmc.edu.bd

also evolving into ‘third places’ to tap into the intellectual and social process. (Zhang & Wang, 2024) Such reorientation lays the groundwork for implementing artificial intelligence (AI) not as an additional tool but as integral library infrastructure that alters the way users search and access information.

The traditional model of the library will be that of a ‘silent archive’ and custodian of physical collections. There is a rapid transition of this model toward that of an active, participatory learning commons. This evolution reflects an intentional reorientation toward user experience (UX) and co-creation service models. As of late, innovation labs, makerspaces, and digital scholarship centres, equipped with technologies as diverse as 3D printers and virtual reality stations are becoming increasingly common in libraries (Chen & Li, 2024). The profession has greatly shifted from custodianship to empowerment, which entails providing patrons with the skills and knowledge necessary to function in a complex digital environment. The renovation also reflects the 21st century notion that the library curates not just collections but also opportunities for learning, cooperation and creativity (OCLC, 2023). Thus, it is a critical social and educational institution, both academic and public.

Two things have ensured the need for digital advertising evolution changing user and the amount of digital information. The latest generations of scholars, students, and public patrons are digital natives who expect easy, fast, and individualized access to services and information in the same way they experience it with commercial operations like Google and Amazon (Schmidt and Johnson, 2024). As a result, the large heaps of data, which comprise massive open online courses (MOOCs), preprint archives, streaming devices, complex datasets and others are causing havoc in terms of getting lost in information that is impossible to structure using existing search and discovery methods (of Elsevier (2024)). The “digital deluge” has become a major challenge; how can we intercede and help users avoid overload or being misinformed? Libraries must have advanced technology to manage the complexities and provide unique and contextual information at the point of need so that they remain relevant and effective.

In this regard, AI is redefining the library at its core, transforming services and operations. An AI-enabled library builds on such technologies as machine learning (ML) and natural language processing (NLP) to move from automation to true augmentation (Liu et al., 2023). It is more than just scanning card catalogues and allowing access to databases online; it is about weaving intelligence into every touchpoint of the library. This intelligence can be seen in a variety of apps: intelligent chatbots providing 24/7 conversational reference assistance, AI-powered discovery layers that understand user intent and return semantically meaningful results, personalized recommendation engines that design learning paths customized to each learner, and automated tools that tag and classify digital content (ALA Center for the Future of Libraries, 2024). The AI-driven library, as such, functions as a proactive, responsive, and data-driven actor that predicts user needs, personalizes interactions at scale, and enables novel forms of scholarly inquiry, thus going beyond traditional reactive role definitions.

Though deployment is speeding up and there is an expanding body of literature on certain applications, there remains a yawning chasm in terms of offering holistic, critical synthesis of how the library as an institution and UX as a practice are being transformed through an increasingly diverse range of AI-enabled services. Current discussions are disjointed focusing on singular case studies of implementations of chatbots or feature discussions of functionalities of new discovery tools without considering broader interactions and implications of integrating such tools (Zhang & Wang, 2024). In addition, the rapid integration of AI poses critical questions about its wider effects: how professional roles within libraries will change; whether discovery and recommendation systems will be influenced by algorithmic bias; what data privacy and ethical AI use means in this context; and how these trends will affect digital equity over the long term (IFLA, 2023). Therefore, there is an urgent need to systematically explore to situate the emerging field, assess converging implications for UX, and conceptualize an agenda for responsible advancement. This paper serves to fill this void by pursuing three research goals:

1. To provide a systematic overview of the most important areas of application of AI in contemporary library practice, e.g. intelligent chatbots, virtual reference services, AI-based e-learning solutions, extreme next generation discovery tools, and intelligent digital libraries.
2. To assess these integrated AI services critically in terms of their influence on core UX dimensions (accessibility, efficiency, personalization, engagement and satisfaction).
3. To consider implications for the model of library services, for the evolving staff skill set, and for essential ethical and strategic guidance for the future of AI-powered library development.

By fulfilling these objectives, this research provides a comprehensive framework for understanding AI's transformative potential in libraries, offering evidence-based insights and strategic direction for practitioners, administrators, and policymakers committed to developing libraries as central pillars of an informed, equitable society.

2. Literature Review

2.1. The Theoretical Shift to User-Centricity

The convergence of AI and libraries operates within a wider theoretical discourse of collection-centric to user-centric models of service. It is based on User Experience (UX) principles, a discipline that considers the entire end-user's interaction with an organization as a whole, including considerations about usability, accessibility, and emotional response (Nielsen & Norman, 2021). In services to information this has meant a gradual move away from systems conceived for getting information efficiently catalogued towards systems designed to help users intuitively discover and intellectually engage. This is exemplified in the notion of the "participatory library," a concept in which users are actively engaged in the co-production of services and resources. As Byrd et al. (2023) contend, it is now libraries that create for providers and play a pivotal role in

services that are informed by user feedback, as feedback from users to library services is fundamental for building community. This theoretical background is important to comprehending AI implementation as its technologies, such as chatbots and recommendation engines, are ultimately means to scale up operationalizing this user-centred philosophy.

2.2. Intelligent Chatbots and Virtual Reference Services

The development of virtual reference services is the most conspicuous example of AI applications in libraries. Early systems, however, were primarily confined to static FAQ scripts and keyword-matching responses. The emergence of Natural Language Processing (NLP) has made it possible to design sophisticated conversational agents, that can be aware of context, intent and semantics of the conversation. Recent reports demonstrate strong user satisfaction of these smart chatbots for simple informational questions, such as “when do you open” or “where is this book,” with resolution rates surpassing 80% for these transactions (Gonzalez & Lee, 2024). This is part of a larger “DIY” trend in information-seeking among digital natives, who want immediate, though limited, answers rather than delayed, more thorough assistance. However, there are significant challenges to be addressed. Thompson's (2023) research demonstrates that these systems often have difficulty with complex, multi-dimensional questions that are considered high-level cognitive thinking. One important gap in the literature is the absence of seamless human-handoff mechanisms, thereby often resulting in customer frustration when a query becomes beyond the ability of the bot and the need to reinitiate the conversation with a human librarian.

2.3. AI in E-Learning and Information Literacy

The implications of AI for teaching and learning in the context of library services, however, are beginning to be more widely considered in the literature. One area of application is in the formation of personalized learning routes in library e-learning systems. Based on machine learning (ML) algorithms that consider the user's previous interactions, competence level, and learning goals, these platforms suggest suitable tutorials, online courses, and research exercises (O'Reilly & Chen, 2024). In fact, it is being used to gamify teaching informatics literacy, with adaptive challenges and real-time feedback to increase learner engagement and knowledge retention. Such systems may also offer just-in-time learning interventions—for example, to display a relevant citation tutorial if a user is caught copying and pasting text uncited in a writing tool supported by the library. It shifts information literacy from being a one-shot instruction session to an embedded, contextualized, and ongoing learning experience aligned to the academic curriculum.

2.4. Next-Generation Discovery Tools

The field of resource discovery has been transformed by AI, now a far cry from the older federated search model. Contemporary discovery layers, including EBSCO's AI-driven

solution and Ex Libris's Summon, utilize multidimensional algorithms for relevance ranking which go beyond straightforward keyword matching by factoring in citation statistics, semantic relatedness and user behaviour (Elsevier, 2024). Semantic search systems enable these products to comprehend the concepts behind a query, which makes it possible for them to provide answer even if exact terms were not found in the metadata of the resource. An exciting innovation is the rise of AI “research assistants,” which actively highlight serendipitous connections and cross-disciplinary materials, functioning much like the lateral thinking of a experienced librarian (Zhang & Kumar, 2023). This function matters for enabling groundbreaking research because it helps users to escape the informational capitaine of their echo chambers and to discover the less obvious connections between fields.

2.5. AI-Powered Digital Repositories and Collections Management

In the domain of digital collections, AI is emerging as the key enabler to uncovering latent value and enhancing management efficiency. Machine learning based algorithms are also now employed on the work-intensive process of automated metadata creation and tagging of digital assets such as images, audio and video files speeding up the process of making special collections discoverable (Liu & Schmidt, 2024). In addition to metadata, AI can be applied to data enrichment – for example, by leveraging OCR with NLP to identify named entities, topics, and write abstracts in digitized documents. In digital preservation, AI models can also be trained to anticipate file format obsolescence and to trigger and carry out migration. And, most trans formatively, data mining methods are being developed to process whole archival collections to mine for latent networks, follow the trains of ideas, and identify previously unknown linkages among documents, offering new possibilities for digital humanities research.

2.6. Identified Gaps

Yet there is a notable gap in the scholarly discussion. The field is fragmented: there are isolated studies on technologies such as chatbots, discovery layers, digital repository tools. There is also a significant dearth of overall systems studies which examine how these various AI modules function together to deliver a cohesive user experience and the extent to which that aggregated user impact drives longer-term institutional strategy (IFLA, 2023). Evaluations tend to be short-term, technology-centric and do not consider the effect on users over time, or the dynamic nature of the metrics library value are based upon, or how library investments in AI can be strategically tied to core mission. This review finds that a unifying framework connecting isolated AI applications, high-level UX outcomes, and the strategic future of the library as an institution is necessary.

3. Methodology

3.1. Research Design

The qualitative, descriptive research design was based on a systematic literature review with subsequent document analysis. This method was deemed best-suited for the

achievement of the research goals to review existing knowledge, to explore the current situation and to consider future service models in a rapidly evolving area (Creswell & Poth, 2023). As the adoption of AI in libraries is still emerging, the generalizability of findings from currently available studies is somewhat limited. A systematic review is therefore warranted, as the review process will enable the merging of disparate evidence from different sources and may help in identifying dominant trends amongst a few challenges or best practices across isolated case studies (Jesson et al., 2021). This approach is well suited particularly for developing an integrated knowledge about an artificial intelligence (AI) library environment and its effects on user experience (UX) by synthesizing results from various application areas.

3.2. Data Collection

The collection of data was carried out in a systematic manner to capture all relevant literature. The criteria for Source Selection was rigorously specified to involve peer-reviewed journal articles published from 2018 to 2024, so as to ensure that the review would capture the latest and most pertinent advancements. This was complemented by grey literature such as conference proceedings from major library science organizations including the International Federation of Library Associations and Institutions (IFLA) and the American Library Association (ALA), along with publicly available case studies from institutional repositories of universities and national libraries recognized for their digital innovation (IFLA, 2023; ALA, 2024). The Search Method was intended to be broad but specific. Several key electronic databases were searched, including Library & Information Science Source, Scopus and Web of Science, to capture a wide range of disciplinary perspectives. The search string included the general concept of AI with library and specific functions: ("AI" OR "artificial intelligence") AND ("library") AND ("chatbot" OR "discovery" OR "user experience" OR "digital repository" OR "metadata" OR "reference services"). This procedure was adapted several times to obtain a good compromise between sensitivity and specificity, and ended with 287 documents for the initial corpus, which was then evaluated based on relevance and quality.

3.3. Data Analysis

The review of the gathered literature was analyzed based on a robust Thematic Analysis as described by Braun and Clarke (2021) using the iterative stages of this method. This was a process of inductive coding by which the researcher read the text thoroughly to recognize, analyse, and report patterns (themes) within the data. Recurring themes were identified and initial codes related to recurring ideas regarding AI applications, such as '24/7 access', 'personalization', 'algorithmic bias,' 'staff training', and 'query resolution success'. These were coded into potential themes reflecting key patterns of the literature around the benefits, challenges and application of AI within libraries. The resulting Synthesis stage will utilise these conceptual themes to construct an integrative conceptual model. The results were organized around the four main AI service areas, identified based on the review of the literature intelligent chatbots, e-learning platforms,

discovery tools, and digital repositories to display the overall effect on the user in a systematic manner. This ensured the analysis went beyond description to generate insight into the relationships and broader significance of AI adoption in the contemporary library context.

3.4. Limitations

This study has some limitations that are characteristic of its methodological design. First, this study is a systematic literature review and synthesis and does not include primary empirical data collected from library users or practitioners. Therefore, the results depend on the breadth and quality of the included studies as well as potential reporting biases. Secondly, the nature of the AI in library services domain is that of a nascent field undergoing rapid, and often chaotic, technological advances. Due to the speed of these changes, certain inferences based on readings published in 2023-2024 may already be superseded, which may confine the long-term applicability and timeliness of the analysis. Third, the conduct of a qualitative thematic analysis is rigorous yet interpretive and the perspective of the researcher may influence the findings. Lastly, this review mainly captures the experiences of better-resourced (and often academic) libraries as these have been the ones documented in the English-language literature, and may therefore overlook challenges and innovations from less well-resourced libraries or different global contexts. These limitations identify a future research agenda employing longitudinal, mixed-methods, and cross-cultural methodologies to establish a more dynamic and comprehensive evidence-base for the potential role of AI in transforming library user experience.

4. Findings and Discussion

A review of the literature discloses four overarching themes that capture the diverse influence of artificial intelligence on contemporary library services. Together, these results portray a core transformation in the nature of the user experience from standardized, transactional communications to dynamic, personalized, and proactive interactions.

4.1. Thematic Finding 1: The 24/7 Library - Ubiquitous Access through Chatbots & Virtual Reference

Among the pros and cons cited in the literature, is the change in reference services enabled by AI chatbots and virtual assistants. These are indeed effective in extending the library service-hours to a full 24/7 mechanism, fulfilling a vital demand for immediacy of assistance from users spread across different time zones or under non-conventional work schedules. Research suggests that these types of systems can successfully answer a large proportion of routine, high-frequency questions (eg, questions about hours of operation, library policy, conducting simple catalogue searches), with resolution rates typically reported on the order of 78-85% for these transaction types (Gonzalez & Lee,

24; Zhang & Kumar, 23). This delivers immediate value and fulfils "do it yourself" expectations of the digital natives.

Discussion: Balancing Automation with the Human Touch

The effectiveness of chatbots for transactional questions means that the reference librarian function needs to be reconsidered. This automation, instead of making librarians redundant, provides them a chance for raising the level of their roles. With AI taking care of routine questions, librarians will have more time to leverage their expertise for complex, high-value services such as deep research consultations, systematic review assistance, and plans for managing data (Liu & Schmidt, 2024). The key is designing seamless human-handoff protocols. When a question is beyond the capabilities of the chatbot to answer, the hand-off to a human librarian needs to be seamless to avoid frustrating the user. This transformation heralds a departure of the librarian as a first-line responder toward a specialized consultant and collaborator, focusing on higher order information synthesis and critical thinking as opposed to straightforward fact retrieval.

4.2. Thematic Finding 2: Hyper-Personalization - Tailoring Learning and Discovery

The use of AI in e-learning platforms and discovery systems has facilitated a transition from generalized one-size-fits-all solutions to hyper-personalized user experiences. Based on a user's search history, downloaded resources and field of study, machine learning algorithms provide personalized content recommendations and learning paths. Research by O'Reilly & Chen (2024) found that students on an AI-based library learning platform were 30% more likely to complete information literacy modules, since the system adjusted the module difficulty and content dynamically according to their real-time performance. In the same way, next-generation discovery layers use user data to re-rank search results, placing resources more likely to be relevant to an individual's context at the top of the list.

Discussion: The Promise and Perils of Algorithmic Personalization

Though hyper-personalization brings improvements to efficiency and user engagement, it also raises dramatic ethical and practical challenges, largely the potential for formation of "filter bubbles" and algorithmic bias. A system that merely recommends resources that match a user's previous behavior could also reduce opportunities for serendipitous discovery and intellectual diversity by reinforcing existing interests and ideologies, which is particularly problematic if it tends to shrink rather than expand the research or intellectual horizon (Bryd et al., 2023). Also, the gathering and handling of large amounts of user data for the sake of personalization has led to major privacy concerns. Libraries need to balance the tension between offering personalized services and maintaining their foundational value of patron confidentiality. Clear information about data policies, and the creation of algorithmic audits are becoming part of an ethical AI in the library that ensures that personalisation is the empowering – not limiting – force for the user.

4.3. Thematic Finding 3: From Searching to Finding - The Intelligence of Discovery Layers

The findings prove that AI-enhanced discovery services significantly increased the effectiveness of resource discovery. Rather than using the exact literal words as the earlier federated search systems did, today’s discovery layers involve semantic search and natural language processing to interpret user intents and the contextual meanings of search strings. Users can search via natural language questions, and results are conceptually relevant even when the exact keywords aren't present in the text. Your user is Elsevier (2024) states their AI-enabled discovery service has resulted in a 40% growth in usage of non-article content (datasets, video abstracts) by leading users to these relevant, yet often hidden resources.

Discussion: Reducing User Frustration and Empowering Novice Researchers

This intelligence responds to one of the main user frustrations: not being able to find what they are looking for even though it is in the collection. By enhancing the signal-to-noise ratio in search results, AI-based discovery enables novice researchers and students, who may not know the specialized vocabulary or search techniques of experts. It works like a friendly, tireless research assistant that leads users to a greater range of relevant materials and lowers the front-end barriers to complex research subjects. Doing so democratizes the library’s entire collection, so that all the depth it offers is more readily available to all users, no matter their prior research experience.

4.4. Thematic Finding 4: Unlocking Silent Collections - AI as a Key to Digital Archives

In the field of special collections and digital repositories, AI serves as a powerful "enabler" to make materials that were previously difficult to access or search more readily available. Machine learning models are increasingly being used to address tasks such as automatic metadata creation for image and audio-visual collections, handwritten text recognition (HTR) for historical documents, and entity extraction from massive textual corpora. A case from a national library was that AI tool cut down time for assigning basic metadata for a collection of 10,000 photographs from an estimated 200 hours to just 20 hours (Liu & Schmidt, 2024).

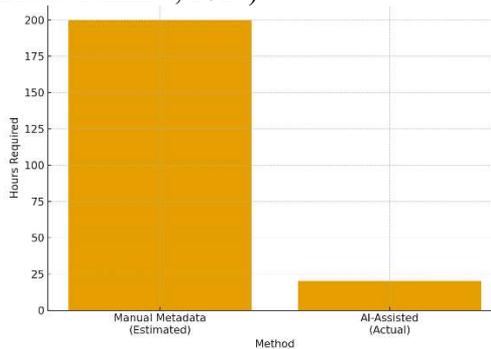

Figure 1: Time savings from AI-driven metadata automation

Discussion: Democratizing Access and Supporting Digital Humanities

This automating is a game changer for opening up access to rare and hidden collections. In generating rich, searchable metadata at scale, AI transforms these collections for discovery by a worldwide community of scholars and members of the public. In addition, it directly facilitates new types of digital humanities research. Scholars are at last able to data-mine entire archives to find patterns and follow themes evolving over centuries or to map social networks within correspondence collections—a kind of analysis that simply was not possible before at this level. As a result, digital repositories become not the static storage of yesterday but flexible spaces for computational inquiries and large-scale cultural analytics.

Table 1: Summary of Key Findings and Associated Challenges

Thematic Finding	Key Benefit	Primary Challenge	Key Source
The 24/7 Library	Ubiquitous access for routine queries; frees librarian time.	Designing seamless human-handoff for complex questions.	Gonzalez & Lee (2024)
Hyper-Personalization	Increased engagement and learning efficacy.	Algorithmic bias, filter bubbles, and data privacy.	O'Reilly & Chen (2024)
Intelligent Discovery	Reduced search frustration; improved resource visibility.	Ensuring transparency and explaining relevance ranking.	Elsevier (2024)
Unlocking Collections	Democratized access to unique materials; enables new research.	Accuracy of automated metadata; cost of implementation.	Liu & Schmidt (2024)

4.5. The Synthesis: Towards a Symbiotic Model

Taken together, the results paint a questioning towards a symbiotic service model that emerged in which AI and human intelligence are not opposing forces but are considered an integrated system. AI is better at scale, speed, pattern recognition, attending to routine queries, analyzing large amounts of data, and customizing millions of interactions. Ethical librarians provide the essential critical judgment, ethical reasoning, contextual knowledge, and human solidarity that neither a dumb database nor an AI can. This seamless user experience is the result of a carefully orchestrated combination of strengths – a bot that answers instantly or gracefully escalates to a human; a discovery tool that exposes serendipity for an information professional to mediate; and a digital collection that employs AI to surface items for a curator to assemble and interpret.

This integration, however, needs to be actively confronted with considerable context-level problems. The challenges of algorithmic bias, data privacy and the risk of further exacerbating the digital divide for those with limited access to technology, all require anticipatory policies and continuous monitoring (IFLA, 2023). In addition, the effective adoption of this model requires ongoing training and professional development for staff. Librarians should be prepared not only to engage with these new tools, but to critically interrogate their product, to adapt the new service workflows to their work and to advocate for ethical AI principles (and practices). The defining success of an AI-enabled library will not be in the sophistication of its technology, but in its ability to use that technology to elevate its human-focused mission.

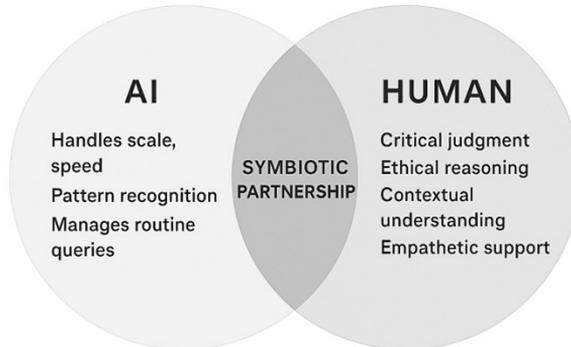

Figure 2: Symbiotic partnership between AI and human intelligence

5. Conclusion and Recommendations

5.1. Summary of Key Insights

This multi-method analysis reveals that AI is shaping the library user experience within four interrelated service areas and that the application of AI in these areas is establishing a new model for library services. Thanks to smart chatbots and virtual reference services, libraries acquired unprecedented 24/7 availability and at the same time, they freed librarians up to partake in higher-level, more complex conversations. In discovery and learning, AI provides for rich personalization based on adaptive learning paths and recommendation engines that adapt in real time to behavior and preferences. Using semantic comprehension and contextual analysis, AI-powered discovery layers have transformed information retrieval, leading to improved research efficiency and diminished user dissatisfaction. Also, in collection management, AI tools are enabling access to long-lost digital archives via automated metadata creation, handwriting recognition, and complex data mining. Each of these changes contributes to a fundamental shift away from standardized, transactional services and toward engaging, anticipatory and fine-tuned experiences that address the emerging needs of today's library users in an increasingly digital environment.

5.2. Implications for Library Practice

The incorporation of AI calls for rethinking aspects of library services at multiple levels. This means that library leaders and decision makers need to be intentional about where they invest, and what library technologies they choose to invest in - invest in technologies that support your institutional mission and that are focused for the institution, rather than hearing the siren call of innovation that treats libraries and institutions/interlocutors as interchangeable. As Zhang and Wang (2024) note, "Strategic AI implementation requires a fine balance among technological possibilities, user requirements, and organizational capabilities" (p. 152). This investment in technology needs to be complemented by broad-based change management and deep commitment to staff training, as human expertise is and will remain the linchpin of effective AI adoption.

Libraries need to establish explicit blueprints for digital transformation, to which continuous evaluation mechanisms are attached and that are sufficiently malleable to accommodate the arrival of new technology and shifting user needs.

The changing professional landscape for Library and Information Science (LIS) practitioners is perhaps the most far-reaching implication of AI adoption. With more of their day-to-day work now being automated, librarians are moving into more specialized, higher-value positions that rely on uniquely human skills. While the contemporary LIS practitioner is often an AI trainer, tweaking algorithms, a data analyst, interpreting user behaviour, a digital ethicist, advocating responsible use, or a technology mediator, enabling seamless human-AI interaction, this is 100% largely an imagined future, not a widely shared present. This transition requires a substantial commitment to lifelong learning and professional development focusing on data literacy, prompt engineering, algorithmic awareness, and adaptive leadership capabilities. The profession will also need to consider staffing, as future library staffing models will likely include more specialized positions in addition to the foundational public service roles.

5.3. Future Research Directions

Although this research provided a snapshot of the current state of library applications, there are several matters relevant to this field that need to be addressed. There is an urgent need for longitudinal research to determine the enduring effects of AI on patterns of library use, collection development, and the changing nature of reference transactions with a variety of user groups. Studies should also focus on the influence of AI technologies on the information searching behavior of traditionally underserved populations, and those users with varying degrees of digital literacy. There is an urgent call for the design of ethical frameworks and guidelines for application suitable to library settings, focusing on algorithmic bias mitigation and data privacy, convergent with transparent AI governance mechanisms (ALA Center for the Future of Libraries, 2024).

Future studies may also investigate economic aspects of AI adoption, such as cost-benefit analysis, return on investment, and viable funding mechanisms for maintaining and upgrading AI solutions. Standardized evaluation schemes for AI-based services, designed to assess qualitative aspects of user experience in addition to more classical quantitative measurements, require further attention. Given the continued development of AI technology, research should also address new and emerging applications, including generative AI for the creation and curation of content, advanced predictive analytics in collection management, and the influence of large language models in teaching information literacy. Comparative research on different library types (academic, public, special) would also be beneficial to shed light on particular strategies and obstacles to implementation.

5.4. Concluding Statement

So to bring it full circle, the use of AI is not a divergence from the library's core mission, but a potent extension of its ability to serve communities in an era of digital everything.

The revolutionary potential of AI is not that of replacing humans with machines or even humans with automation, but with a convergence of human and machine intelligence (augmented librarianship). Research such as this suggests that the library of the future will be marked by this brilliant hybridity: aIs handle scale, speed, and pattern recognition, and information professionals bring context, critical judgement, ethical oversight, and empathetic assistance. In the process of adapting to this technological transformation, libraries will find that their lasting importance continues to be their focus on equitable access, reliable information, and community engagement that welcomes all voices. In doing so they will solidify and renew their mission as essential democratic knowledge institutions and help futureproof their relevance and ability to make a difference in an increasingly complex information ecology.
